

## WATER TECHNOLOGY: EXECUTIVE SUMMARY

- ❑ Water quality and scarcity problems (“water stress”) are reaching critical proportions worldwide, increasing governmental regulatory responses (mandates, not price support)
- ❑ Different developmental stages drive different investment priorities and approaches in different geographies; technological solutions are only a small part of the solution, and even smaller part of CapEx (vs. infrastructure, services etc.)
- ❑ Technology (“water tech”) promises to transform the huge (~US\$450bn annual investment) water sector, but faces significant legacy challenges (infrastructure, regulation, incumbents, conservatism); scale-up risk/costs/timeframes represent another major impediment
- ❑ While the Agricultural sector dominates water consumption (& waste), the Industrial sector is a quicker adopter of new technologies
- ❑ An increasing interdependence is emerging between the water and energy sectors (“water-energy nexus”), driven in large part by increasing non-traditional fuel extraction (fracking, tar sand ...) as well as (energy-intensive) water treatment/production
- ❑ Innovation and investment opportunities exist in most major segments – wastewater treatment (WWT), desalination, conveyance systems, leakage avoidance/remediation – as well as new segments (“smart” water, waste-to-energy ...) ...
- ❑ ... but a proliferation of different technologies/approaches for a highly fragmented, insular customer base reduces business scaling potential
- ❑ From a low base, there is increasing VC interest in water technology start-ups, although long project/customer leadtimes and high CapEx (pilot projects) are a frequent barrier
- ❑ High fragmentation of water SMEs presents significant potential for consolidation and bolt-ons for large industrial groups
